(57) **ABSTRACT**

In one aspect, a method of fabricating a semiconductor device is provided. The method includes forming at least one capping layer over epitaxial source/drain regions of a PMOS device, forming a stress memorization (SM) layer over the PMOS device including the at least one capping layer and over an adjacent NMOS device, and treating the SM layer formed over the NMOS and PMOS devices to induce tensile stress in a channel region of the NMOS device.

CHANNEL-STRESSED SEMICONDUCTOR DEVICES AND METHODS OF FABRICATION

BACKGROUND OF THE INVENTION

[0001] 1. Field of the Invention

[0002] The present invention generally relates to semiconductor devices and to the fabrication thereof, and more particularly, the present invention relates to semiconductor devices utilizing stress memorization, and to methods of fabricating the same.

[0003] 2. Description of the Related Art

[0004] Transistor devices have been reduced in size to the extent where scaling limitations (e.g., gate oxide leakage and short channel effects) are becoming a significant roadblock to further device integration. The consensus in the art is that improvements in "channel mobility" can largely overcome or reduce the adverse effects these scaling limitations. Channel mobility generally refers to the ease with which electrons (for NMOS devices) and holes (for PMOS devices) are capable of being transferred within the channel region of the transistor device.

[0005] One technique being explored to enhance channel mobility is to induce strain within the channel region to thereby physically elongate or compress atomic bonds. In particular, tensile stress within the channel region of an NMOS device has been found to improve electron mobility in the channel, while compressive stress within the channel region of a PMOS device can improve hole mobility within the channel.

[0006] "Stress memorization" (SM) is one technique that may be utilized to induce tensile stress within the channel region of an NMOS device. Here, an SM layer is deposited over the gate structure of the NMOS device. The SM layer is generally formed of an insulating material, such as SiN. During a subsequent anneal, tensile stresses induced in the SM layer cause compressive stresses in the gate electrode and in the adjacent source and drain regions. These compressive stresses cause tensile stress to be induced in the channel region of the NMOS device. These stresses are "memorized" during the anneal process, and the SM layer is then removed.

[0007] However, the channel region tensile stress induced by the SM layer can adversely impact the operating performance of an adjacent PMOS device. Accordingly, the SM layer must be patterned to remove the portion thereof overlying the PMOS device prior to the anneal process. This requires execution of additional masking and etching processes, thus increasing costs and fabrication times.

[0008] In the meantime, one technique utilized to induce compressive stress within a PMOS device is to epitaxially grow SiGe source/drain regions on opposite sides of the channel region. The SiGe epitaxial regions have a larger lattice constant than that of the intervening channel region. The resultant tensile stress in the epitaxial regions induces a compressive stress in the channel region of the PMOS region. Hole mobility in the channel therefore increases, which in turn enhances the operating speed of the PMOS transistor.

[0009] Again, however, in order to avoid degradation in the performance of the PMOS transistor, it is necessary to perform the costly and time consuming steps associated with patterning the SM layer to remove the same from over the PMOS device prior to annealing the SM layer to induce tensile stress the NMOS channel.

SUMMARY OF THE INVENTION

[0010] According to an aspect of the present invention, a method of fabricating a semiconductor device is provided. The method includes forming at least one capping layer over epitaxial source/drain regions of a PMOS device, forming a stress memorization (SM) layer over the PMOS device including the at least one capping layer and over an adjacent NMOS device, and treating the SM layer formed over the NMOS and PMOS devices to induce tensile stress in a channel region of the NMOS device.

[0011] According to another aspect of the present invention, a method of manufacturing a semiconductor device is provided. The method includes providing a substrate including an NMOS region and a PMOS region, and gate structures respectively located over the NMOS region and PMOS region, forming first and second trenches in the substrate adjacent the gate structure of the PMOS region, forming epitaxial source and drain regions within the first and second trenches, respectively, forming at least one capping layer over the epitaxial source and drain regions, forming a stress memorization (SM) layer over the NMOS and PMOS regions, including the at least one capping layer, and annealing the SM layer formed over the NMOS and PMOS regions.

[0012] According to still another aspect of the present invention, a method of manufacturing a semiconductor device is provided. The method includes interposing at least one capping layer between a PMOS device and a stress memorization (SM) layer, and treating the SM layer to induce tensile stress in an NMOS device located adjacent the PMOS device.

[0013] According to yet another aspect of the present invention, a semiconductor device, is provided. The semiconductor device includes a PMOS device and an NMOS device. The PMOS device includes a gate structure located over a substrate, epitaxial source and drain regions located in the substrate adjacent the gate structure, and a channel region located between the epitaxial source and drain regions. The NMOS device includes a gate structure located over the substrate, first and second recesses located in a surface of the substrate adjacent the gate structure, source and drain regions formed in the substrate and below the first and second recesses of the substrate, and a channel region located between the source and drain regions.

BRIEF DESCRIPTION OF THE DRAWINGS

[0014] Aspects and features of embodiments of the present invention will become readily apparent from the detailed description that follows, with reference to the accompanying drawings, in which:

[0015] FIGS. **1**A through **1**I are cross-sectional views for use in explaining a method of manufacturing a semiconductor device according to an embodiment of the present invention;

[0016] FIGS. **2** and **3** are diagrams illustrating relative Ge concentrations in a depth direction of layers according to an embodiment of the present invention;

[0017] FIGS. **4**A and **4**B are cross-sectional views for use in explaining a method of manufacturing a semiconductor device according to another embodiment of the present invention;

[0018] FIGS. **5**A through **5**F are cross-sectional views for use in explaining a method of manufacturing a semiconductor device according to another embodiment of the present invention; and

[0019] FIG. **6** is a diagram illustrating a relative Ge concentration in a depth direction of layers according to an embodiment of the present invention

DETAILED DESCRIPTION OF EMBODIMENTS

[0020] The present invention will now be described by way of preferred, but non-limiting, embodiments of the invention.

[0021] For ease of understanding and to avoid redundancy, like reference numbers refer to the same or similar elements throughout the drawings. Also, while the drawings contain a number of cross-sectional views, it will be understood that the views are not necessarily drawn to scale, and that the relative thicknesses of the illustrated layers may be exaggerated for clarity. Further, when a layer is referred to as being formed "on" another layer, it can be directly on the other layer or one or more intervening layers may be present. In contrast, if a layer is referred to as being "directly on" another layer, then no intervening layers or elements are present. Other words used to describe the relationship between elements should be interpreted in a like fashion (e.g., "between" versus "directly between," "adjacent" versus "directly adjacent," "connected" versus "directly connected," etc.).

[0022] A method of fabricating a semiconductor device according to a non-limiting embodiment of the present invention will now be described with reference to FIGS. **1**A through **1**I of the drawings.

[0023] Initially, referring to FIG. **1**A, device isolation regions **110** are formed to define an NMOS region and a PMOS region of a substrate **100**. Various types of isolation regions and fabrication techniques thereof are well-known in the art. In the illustrated example, each device isolation region **110** is formed in a trench **100***a,* and includes an oxide liner **111**, a nitride liner **112**, and an isolation layer **114**. Also, as shown in FIG. **1**A, a p-well **101** is formed in the NMOS region of the substrate **100**, and an n-well **102** is formed in the PMOS region of the substrate **100**.

[0024] Next, gate structures are formed over the p-well **101** and n-well **102**. A variety of gate structures and fabrication techniques thereof are well-known in the art. In the illustrated example of FIG. **1**A, each gate structure includes a stacked structure of a gate insulating layer **123**, a gate electrode **125**, and a gate capping layer **127**. The gate insulating layer **123** may, for example, be formed of SiO_2, HfO_2 or Ta_2O_5. The gate electrode **125** may, for example, be formed of polysilicon. The gate capping layer **127** may, for example, be formed of SiN, and may, for example, have a thickness of 300 to 500 Å.

[0025] Still referring to FIG. **1**A, by utilizing the gate structures as a mask, n-type source/drain extensions ne are formed in the p-well **101**, and p-type source/drain extensions pe are formed in the n-well **102**. The extensions ne and pe may be formed using conventional masking and implantation processes.

[0026] Referring now to FIG. **1**B, sidewall spacers are formed on the gate structures of FIG. **1**A. A variety of sidewall spacers and fabrication techniques thereof are well-known in the art. In the example of FIG. **1**B, each sidewall spacer includes a first L-shaped spacer **132**, and a second spacer **134**, which together cover a portion of the surface of the substrate **100** adjacent the gate structures. The first L-shaped spacer **132** may, for example, be formed of SiON, and the second spacer **134** may, for example, be formed of SiN or SiON.

[0027] Turning to FIG. **1**C, a resist mask **140** is formed (e.g., by photolithography) to cover the NMOS region and expose the PMOS region of the substrate **100**. The resist mask **140** may, for example, be formed of a layer of SiN or SiON, and may, for example, have a thickness of 100 to 150 Å.

[0028] Next, still referring to FIG. **1**C, trenches T_SD are formed in the substrate **100** on opposite sides of the gate structure of PMOS region. In the example of this embodiment, the trenches T_SD are formed by anisotropic etching, using the gate and sidewall structure as a mask. The trenches T_SD may, for example, be formed to a depth of 300 to 1200 Å. P-type impurities are then implanted to form p-type source/drain regions psd at bottom and sidewalls of the trenches T_SD.

[0029] Referring now to FIG. **1**D, epitaxial layers **151** are grown in the trenches T_SD of the PMOS region. In the example of this embodiment, the epitaxial layers **151** are formed by epitaxial growth of SiGe. Also in the example of this embodiment, the epitaxial layers completely fill the trenches T_SD of the PMOS region, and protrude above a surface of the substrate **100**. P-type impurity doping of the epitaxial layers **151** may, for example, be performed in situ during the epitaxial growth process.

[0030] The epitaxial layers **151** have a larger lattice constant larger than that of the silicon substrate, and as shown in FIG. **1**D, the epitaxial layers **151** are under tensile stress PS_T. The resultant deformation in the epitaxial layers **151** induces a compressive stress PCS_C in the channel of the PMOS region. Hole mobility in the channel therefore increases, which in turn enhances the operating speed of the PMOS transistor.

[0031] Then, as shown in FIG. **1**D, one or more capping layers **153** are formed over the epitaxial layers **151**. In particular, in the example of this embodiment, a first capping layer **153_1** and a second capping layer **153_2** are successively formed over the epitaxial layers **151**. For example, the first epitaxial layer **153_1** may be formed by epitaxial growth of Si to form a silicon epitaxial capping layer. The second epitaxial layer **153_2** may be formed by epitaxial growth of SiGe to form a SiGe epitaxial capping layer. As examples, the first capping layer **153_1** may be formed to a thickness of 30 to 300 Å, while the second capping layer **153_2** may be formed to a thickness of 100 to 500 Å.

[0032] In the case where epitaxial layers **151** and the second capping layer **153_2** are formed of SiGe, a Ge concentration thereof may be characterized by the diagrams shown in FIGS. **2** and **3**. For example, as shown in FIG. **2**, the Ge concentration of the SiGe epitaxial layers **151** may be substantially constant in the depth direction. Alternately, for example, the Ge concentration may gradually decrease in the depth direction as shown in FIG. **3**. In either case, as shown in both diagrams, it is generally preferred that the Ge concentration of the second capping layer exceed that of the SiGe epitaxial layers **151**. As examples, the Ge concentration of the SiGe epitaxial layers **151** may be 10 to 30 at %, and the Ge concentration of the SiGe capping layer **153_2** may be 20 to 40 at %.

[0033] Turning now to FIG. **1**E, a mask **200** is formed (e.g., by photolithography) to as to cover the PMOS region and expose the NMOS region of the substrate **100**. The mask **200** and the gate structure of the NMOS region are then utilized as

masks during ion implantation of n-type dopants to define n-type source/drain regions nsd in the n-well **101**.

[0034] Next, referring to FIG. **1**F, a stress memorization (SM) layer **160** is formed over the NMOS and PMOS regions of the substrate **100**. Herein, an SM layer is defined as a layer of material which, when subjected to external energy, induces tensile stresses NS_{T1} therein. The SM layer **160** may, for example, be an insulating layer such as SiN. In the present embodiment, the external energy is thermal energy, although the invention is not limited thereto. That is, in the present embodiment, when SM layer **160** is annealed, tensile stresses NSTi are created about the gate structures as shown in FIG. **1**F.

[0035] The tensile stresses NS_{T1} of the SM layer induces compressive stresses NS_{C1} in the gate electrode **125** and in the source/drain regions nsd. As a result, tensile stress NCS_{T1} is induced in the channel region of the NMOS device.

[0036] Also illustrated in FIG. **1**F is an etch stop layer **163** which may optionally be interposed between the substrate surface and the SM layer **160**. The etch stop layer **163** may, for example, be formed to a thickness of 50 to 100 Å.

[0037] It should be noted here that the tensile stresses of the SM layer **160** has relatively little or no adverse impact the adjacent PMOS device underlying a portion of the SM layer. This is due at least in part to the presence of the at least one capping layer **153**. That is, the capping layer may reduce the amount of stresses induced in the PMOS device by acting as a physical barrier and/or by reducing the exposed height of the gate electrode **126** over which the SM layer **160** is formed. As such, patterning of the SM layer **160** to remove the same from over the PMOS device is avoided.

[0038] Turning now to FIG. **1**G, the SM layer **160**, the etch stop layer **163** and the second capping layer **153_2** are removed. For example, the SM layer and the etch stop layer **163** may be removed by an etching process, and the second capping layer may be removed using a cleaning solution (e.g., SC-1 and HF). Then, a metal layer **170** (e.g., Co or Ni) is formed over the surface of the substrate.

[0039] Referring to FIG. **1**H, the metal layer **170** (FIG. **1**G) is annealed and reacted with the surfaces of the gate electrodes **125** and **126**, the source/drain regions nsd, and the source/drain regions psd. As a result, corresponding silicide layers **181**, **187**, **183** and **185** are formed. Un-reacted metal is then removed, and an insulating layer **191** (e.g., an SiN layer) is deposited over the substrate surface and then annealed. As represented in FIG. **1**H, the annealed insulating layer **191** acts as a second SM layer. That is, the annealed insulating layer **191** is under tensile stress NS_{T2} about the gate electrode **125**, resulting in compressive stresses NS_{C2} in the source/drain regions nsd, and tensile stress NCS_{T2} in tie channel region of the NMOS device.

[0040] Then, as shown in FIG. **1**I, an interlayer dielectric layer (ILD) **193** is deposited over the surface of the substrate, and contact holes **193***a* are formed in the ILD **193** and insulating layer **191** to expose upper surfaces of the silicide layers **183** and **185** of the source/drain regions nsd and psd. Metal contact plugs **195** are then formed in the contact holes **193***a*.

[0041] Another non-limiting embodiment of the invention will be described next with reference to FIGS. **4**A and **4**B.

[0042] The processes executed to obtain the structure illustrated by FIG. **4**A may be the same as those of previously described FIGS. **1**A through **1**C, expect that the trenches T_SD are formed by isotropic etching (as opposed to the anisotropic etching of FIG. **1**C). As a result, a more rounded trench profile will generally result, and the trenches T_SD will tend to protrude beneath the spacers **132** and **134**. The trenches T_SD may, for example, be formed to a depth of 300 to 1200 Å. P-type impurities are then implanted to form p-type source/drain regions psd at bottom and sidewalls of the trenches T_SD.

[0043] Referring to FIG. **4**B, epitaxial layers **151** are grown in the trenches T_SD of the PMOS region. In the example of this embodiment, the epitaxial layers **151** are formed by epitaxial growth of SiGe. Also in the example of this embodiment, the epitaxial layers completely fill the trenches T_SD of the PMOS region, and protrude above a surface of the substrate **100**. P-type impurity doping of the epitaxial layers **151** may, for example, be performed in situ during the epitaxial growth process.

[0044] As explained previously, the epitaxial layers **151** have a larger lattice constant larger than that of the silicon substrate, and as shown in FIG. **1**D, the epitaxial layers **151** are under tensile stress PS_T. The resultant deformation in the epitaxial layers **151** induces a compressive stress PCS_C in the channel of the PMOS region. Hole mobility in the channel therefore increases, which in turn enhances the operating speed of the PMOS transistor.

[0045] Then, one or more capping layers **153** are formed over the epitaxial layers **151**. In particular, in the example of this embodiment, a first capping layer **153_1** and a second capping layer **153_2** are successively formed over the epitaxial layers **151**. For example, the first epitaxial layer **153_1** may be formed by epitaxial growth of Si to form a silicon epitaxial capping layer. The second epitaxial layer **153_2** may be formed by epitaxial growth of SiGe to form a SiGe epitaxial capping layer. As examples, the first capping layer **153_1** may be formed to a thickness of 30 to 300 Å, while the second capping layer **153_2** may be formed to a thickness of 100 to 500 Å.

[0046] In the case where epitaxial layers **151** and the second capping layer **153_2** are formed of SiGe, a Ge concentration thereof may be characterized by the diagrams shown in FIGS. **2** and **3**. For example, as shown in FIG. **2**, the Ge concentration of the SiGe epitaxial layers **151** may be substantially constant in the depth direction. Alternately, for example, the Ge concentration may gradually decrease in the depth direction as shown in FIG. **3**. In either case, as shown in both diagrams, it is generally preferred that the Ge concentration of the second capping layer exceed that of the SiGe epitaxial layers **151**. As examples, the Ge concentration of the SiGe epitaxial layers **151** may be 10 to 30 at %, and the Ge concentration of the SiGe capping layer **153_2** may be 20 to 40 at %.

[0047] The remaining processes of this exemplary embodiment may be the same as those described above in connection with FIGS. **1**E through **1**F, and a detailed description thereof is omitted here to avoid redundancy.

[0048] Another non-limiting embodiment of the invention will be described next with reference to FIGS. **5**A through **5**F.

[0049] The processes executed to obtain the structure illustrated by FIG. **4**A may be the same as those of previously described FIGS. **1**A through **1**D, except that the capping layer is defined by a continuous silicon epitaxial layer **154** grown on the epitaxial layers **151**, where the silicon epitaxial layer **154** may, for example, be devoid or substantially devoid of Ge atoms. That is, referring to FIG. **6**, in one example the epitaxial layers **151** defining the source/drain regions psd are formed of SiGe, and a Ge concentration is substantially con-

stant in a depth direction, whereas the layer **154** is epitaxial silicon having a Ge concentration of 0 at %.

[0050] Turning now to FIG. **5**B, a mask **200** is formed (e.g., by photolithography) to as to cover the PMOS region and expose the NMOS region of the substrate **100**. The mask **200** and the gate structure of the NMOS region are then utilized as masks during ion implantation of n-type dopants to define n-type source/drain regions nsd in the n-well **101**.

[0051] Next, referring to FIG. **5**C, a stress memorization (SM) layer **160** is formed over the NMOS and PMOS regions of the substrate **100**. Herein, an SM layer is defined as a layer of material which, when subjected to external energy, induces tensile stresses NS_{T1} therein. The SM layer **160** may, for example, be an insulating layer such as SiN. In the present embodiment, the external energy is thermal energy, although the invention is not limited thereto. That is, in the present embodiment, when SM layer **160** is annealed, tensile stresses NSTi are created about the gate structures as shown in FIG. **5**C.

[0052] The tensile stresses NS_{T1} of the SM layer induces compressive stresses NS_{C1} in the gate electrode **125** and in the source/drain regions nsd. As a result, tensile stress NCS_{T1} is induced in the channel region of the NMOS device.

[0053] Also illustrated in FIG. **5**C is an etch stop layer **163** which may optionally be interposed between the substrate surface and the SM layer **160**. The etch stop layer **163** may, for example, be formed to a thickness of 50 to 100 Å.

[0054] It should be noted here that the tensile stresses of the SM layer **160** has relatively little or no adverse impact the adjacent PMOS device underlying a portion of the SM layer. This is due at least in part to the presence of the capping layer **154**. That is, the capping layer may reduce the amount of stresses induced in the PMOS device by acting as a physical barrier and/or by reducing the exposed height of the gate electrode **126** over which the SM layer **160** is formed. As such, patterning of the SM layer **160** to remove the same from over the PMOS device is avoided.

[0055] Turning now to FIG. **5**D, the SM layer **160**, the etch stop layer **163** and a portion of the capping layer **154** are removed. In this case, removal of the portion of the capping layer **154** also results in the formation of a recess R in the substrate surface at the source/drain regions nsd of the NMOS device. The depth of the recess may, for example, be 50 to 150 Å.

[0056] Referring to FIG. **5**E, silicide layers **181**, **187**, **183** and **185** are respectively formed at the surfaces of the gate electrodes **125** and **126**, the source/drain regions nsd, and the source/drain regions psd. (See the previous discussion in connection with FIG. **1**H in this regard.) Un-reacted metal is then removed, and an insulating layer **191** (e.g., a SiN layer) is deposited over the substrate surface and then annealed. As represented in FIG. **5**E, the annealed insulating layer **191** acts as a second SM layer. That is, the annealed insulating layer **191** is under tensile stress NS_{T2} about the gate electrode **125**, resulting in compressive stresses NS_{C2} in the source/drain regions nsd, and tensile stress NCS_{T2} in the channel region of the NMOS device.

[0057] Further, as a result of the formation of the recess R (FIG. **5**D), the channel region of the NMOS device is positioned directly between portions of the insulating layer **191**. Thus, the tensile stress of the insulating layer **191** is directly induced in the lateral direction to the channel region of the NMOS device, thus increasing the tensile stress within the channel region. Channel mobility is thereby enhanced.

[0058] Then, as shown in FIG. **5**F, an interlayer dielectric layer (ILD) **193** is deposited over the surface of the substrate, and contact holes **193***a* are formed in the ILD **193** and insulating layer **191** to expose upper surfaces of the silicide layers **183** and **185** of the source/drain regions nsd and psd. Metal contact plugs **195** are then formed in the contact holes **193***a*.

[0059] While the present invention has been particularly shown and described with reference to exemplary embodiments thereof, it will be understood by those of ordinary skill in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention as defined by the appended claims and their equivalents.

What is claimed is:

1. A method of fabricating a semiconductor device, comprising:

forming at least one capping layer over epitaxial source/drain regions of a PMOS device;

forming a stress memorization (SM) layer over the PMOS device including the at least one capping layer and over an adjacent NMOS device, and

treating the SM layer formed over the NMOS and PMOS devices to induce tensile stress in a channel region of the NMOS device.

2. The method of claim **1**, wherein treating the SM layer includes annealing of the SM layer.

3. The method of claim **1**, wherein the epitaxial source/drain regions induce compression strain in a channel region of the PMOS device.

4. The method of claim **1**, further comprising removing the SM layer after said annealing.

5. The method of claim **4**, wherein the at least one capping layer includes a first capping layer formed on the epitaxial source/drain regions, and a second capping layer formed on the first capping layer.

6. The method of claim **5**, further comprising removing the second capping layer, and performing a silicide process on the first capping layer.

7. The method of claim **4**, wherein the at least one capping layer comprises a single capping layer.

8. The method of claim **7**, further comprising partially removing the single capping layer, and subjecting a remaining portion of the single capping layer to a silicide process.

9. The method of claim **8**, further comprising forming recesses in the substrate adjacent a gate electrode of the NMOS device simultaneously with said partial removal of the single capping layer.

10. The method of claim **1**, further comprising forming the epitaxial source/drain regions by forming trenches adjacent a gate electrode of the PMOS device, and epitaxially growing the source/drain regions within the trenches to induce compression strain within a channel of the PMOS device.

11. The method of claim **10**, wherein the epitaxial source/drain regions comprise SiGe.

12. The method of claim **11**, further comprising in situ doping of the SiGe source/drain regions with a p-type impurity.

13. The method of claim **10**, wherein the at least one capping layer includes a first capping layer formed on the epitaxial source/drain regions, and a second capping layer of SiGe on the first capping layer, wherein a Ge concentration of the second capping layer is greater than a Ge concentration of the SiGe source/drain regions.

14. The method of claim **10**, wherein the trenches are formed by anisotropic etching.

15. The method of claim **10**, wherein the trenches are formed by isotropic etching.

16. The method of claim **1**, wherein the SM layer comprises SiN.

17. A method of manufacturing a semiconductor device, comprising:

providing a substrate including an NMOS region and a PMOS region, and gate structures respectively located over the NMOS region and PMOS region;

forming first and second trenches in the substrate adjacent the gate structure of the PMOS region;

forming epitaxial source and drain regions within the first and second trenches, respectively;

forming at least one capping layer over the epitaxial source and drain regions;

forming a stress memorization (SM) layer over the NMOS and PMOS regions, including the at least one capping layer; and

annealing the SM layer formed over the NMOS and PMOS regions.

18. The method of claim **17**, further comprising removing the annealed SM layer from over the NMOS and PMOS regions.

19. The method of claim **18**, wherein the at least one capping layer comprises first and second capping layer, the first capping layer located between the second capping layer and the epitaxial source and drain regions.

21. The method of claim **19**, wherein said method further comprises removing the second capping layer and subjecting the first capping layer to a silicide process.

22. The method of claim **19**, wherein the epitaxial source and drain regions and the second capping layer comprise SiGe, and the first capping layer comprises Si.

23. The method of claim **22**, wherein a Ge concentration of the second capping layer is greater than a Ge concentration of the epitaxial source and drain regions.

24. The method of claim **17**, further comprising in situ doping of the epitaxial source and drain regions with a p-type impurity.

25. The method of claim **18**, wherein the at least one capping layer includes a single capping layer comprising epitaxial Si.

26. The method of claim **25**, further comprising partially removing the single capping layer, and subjecting a remaining portion of the single capping layer to a silicide process.

27. The method of claim **26**, further comprising forming recesses in the substrate adjacent the gate structure of the NMOS device simultaneously with said partial removal of the signal capping layer.

28. The method of claim **17**, wherein the SM layer comprises SiN.

29. A method of manufacturing a semiconductor device comprising interposing at least one capping layer between a PMOS device and a stress memorization (SM) layer, and treating the SM layer to induce tensile stress in an NMOS device located adjacent the PMOS device.

30. The method of claim **29**, further comprising removing the SM layer and a portion of the at least one capping layer, subjecting a remaining portion of the at least one capping layer to a silicide process, forming a second SM layer over a resultant structure, and annealing the second SM layer to further induce tensile stress in the NMOS device.

31. A semiconductor device, comprising:

a PMOS device comprising a gate structure located over a substrate, epitaxial source and drain regions located in the substrate adjacent the gate structure, and a channel region located between the epitaxial source and drain regions; and

an NMOS device comprising a gate structure located over the substrate, first and second recesses in a surface of the substrate adjacent the gate structure, source and drain regions formed in the substrate below the first and second recesses of the substrate, and a channel region located between the source and drain regions.

32. The semiconductor device of claim **31**, wherein an upper surface of the epitaxial source and drain regions extends above an upper surface of the substrate.

33. The semiconductor device of claim **31**, wherein the epitaxial source and drain regions comprise SiGe.

34. The semiconductor device of claim **31**, further comprising silicide layers located on the epitaxial source and drain regions.
